

FEATURES

Precision power supply monitoring
31 reset threshold options: 1.58 V to 5.0 V
Four reset timeouts: 1 ms, 20 ms, 140 ms, and 1120 ms
Manual reset input
Reset output stage
Push-pull active-low
Guaranteed reset output valid to $V_{CC} = 1\text{ V}$
Power supply glitch immunity
Specified over the -40°C to $+125^{\circ}\text{C}$ temperature range
4-lead SC70 package

APPLICATIONS

Microprocessor systems
Computers
Controllers
Intelligent instruments
Portable equipment

GENERAL DESCRIPTION

The [ADM6384](#) is a supervisory circuit that monitors power supply voltage levels in microprocessor-based systems. A power-on reset signal is generated when the supply voltage rises to a preset threshold level. The debounced manual reset input of the [ADM6384](#) can be used to initiate a reset by means of an external push button or logic signal.

The device is available in a choice of 31 reset threshold options, from 1.58 V to 5.0 V. The minimum reset timeout periods are 1 ms, 20 ms, 140 ms, and 1120 ms.

The [ADM6384](#) is available in a 4-lead SC70 package and typically consumes only $7\ \mu\text{A}$, making it suitable for use in low power, portable applications.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 2.

Parameter	Rating
V_{CC}	-0.3 V to +6 V
$\overline{\text{RESET}}$	-0.3 V to +6 V
Output Current ($\overline{\text{RESET}}$)	20 mA
Operating Temperature Range	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C
θ_{JA} Thermal Impedance, SC70	331°C/W
Soldering Temperature	
Sn/Pb	240°C, 30 sec
Pb-Free	260°C, 40 sec

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

CIRCUIT DESCRIPTION

The ADM6384 provides microprocessor supply voltage supervision by controlling the microprocessor reset input. Code execution errors are avoided during power-up, power-down, and brownout conditions by asserting a reset signal when the supply voltage is below a preset threshold. In addition, the ADM6384 allows supply voltage stabilization with a fixed timeout before the reset deasserts after the supply voltage rises above the threshold. If the user detects a problem with the system operation, a manual reset input is available to reset the microprocessor by means of an external push-button, for example.

RESET OUTPUT

The ADM6384 features an active-low, push-pull reset output. The reset signal is guaranteed to be logic low for V_{CC} down to 1 V.

The reset output is asserted when V_{CC} is below the reset threshold (V_{TH}) or when \overline{MR} is driven low. Reset remains asserted for the duration of the reset active timeout period (t_{RP}) after V_{CC} rises above the reset threshold or after \overline{MR} transitions from low to high. Figure 12 illustrates the behavior of the reset outputs.

Figure 12. Reset Timing Diagram

MANUAL RESET INPUT

The ADM6384 features a manual reset input (\overline{MR}) that, when driven low, asserts the reset output. When \overline{MR} transitions from low to high, reset remains asserted for the duration of the reset active timeout period before deasserting. The \overline{MR} input has a 52 k Ω internal pull-up so that the input is always high when unconnected. An external push-button switch can be connected between \overline{MR} and ground so that the user can generate a reset. Debounce circuitry for this purpose is integrated on-chip. Noise immunity is provided on the \overline{MR} input, and fast, negative-going transients of up to 100 ns (typical) are ignored. A 0.1 μ F capacitor between \overline{MR} and ground provides additional noise immunity.

APPLICATIONS INFORMATION

NEGATIVE-GOING V_{CC} TRANSIENTS

To avoid unnecessary resets caused by fast power supply transients, the ADM6384 is equipped with glitch rejection circuitry. The typical performance characteristic shown in Figure 10 plots V_{CC} transient duration vs. the transient magnitude. The curves show combinations of transient magnitude and duration for which a reset is not generated for 4.63 V and 2.93 V reset threshold devices. For example, with the 2.93 V threshold, a transient that goes 100 mV below the threshold and lasts 8 μ s typically does not cause a reset, but if the transient is any greater in magnitude or duration, a reset is generated. An optional 0.1 μ F bypass capacitor mounted close to V_{CC} provides additional glitch rejection.

ENSURING RESET VALID TO $V_{CC} = 0$ V

Both active-low and active-high reset outputs are guaranteed to be valid for V_{CC} as low as 1 V. However, by using an external resistor with push-pull configured reset outputs, valid outputs for V_{CC} as low as 0 V are possible. For an active-low reset output, a resistor connected between $\overline{\text{RESET}}$ and ground pulls the output low when it is unable to sink current. Use a large resistance such as 100 k Ω to avoid overloading the reset output when V_{CC} is above 1 V.
